## Topic 2

# C++ Review Part II: More on Functions, Variables, Classes

資料結構與程式設計 Data Structure and Programming

09.26.2018

## Part I: Understanding "Functions"

- ◆ Global vs. member functions
- ◆ Function signature, prototype , definition
- ◆ Function parameters, arguments

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

## **Key Concept #1: Global vs. Member Functions**

- Global functions are defined in global scope
  - void f(...) { ... }
  - There is no so-called local functions
- Member functions are defined in class scope
  - void A::f(...) { ... }
  - A member function is called by an object of its class type

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

3

### **Key Concept #2: Function Signature**

- ◆ 4 things to define "function signature"
  - 1. Function name
  - 2. Number of parameters
  - 3. Types of parameters
  - 4. Order of parameters

→ No "return type" (why?)

function names is neither in function signature.

- ◆ There cannot be functions with the same function signature, unless ---
  - 1. Separated by different name spaces
  - Defined as "static" in different file scopes
- However, functions can have the same name, but different signature (overloading)

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

<sup>&</sup>quot;it's a good practice adding 'static' in front of functions that you're sure only you would use it"

# **Key Concept #3: Function Prototype** vs. Function Definition

◆ Think, which one is better?

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

5

#### **Key Concept #4: Default Argument**

- ◆ Note:
  - void f(int x) { ... } // x is f's parameter
  - f(10); f(a); // 10, a as arguments to f()
- ◆ Parameters with default assignments → function with default arguments
  - Can be skipped when calling the function
  - e.g. void f(int x, int y = 0);f(10);
  - Can only appear towards the end of parameter list
  - (Not OK) void f(int x = 0, int y);
- Given a function, its default argument can only be defined ONCE
  - void f(int x = 0);
     void f(int x = 0) { ... } → Compilation ERROR

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

# **Key Concept #5: Parameters in a function**

 When a function is called, the caller performs "=" operations on its arguments to the corresponding parameters in the function

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

8

## Key Concept #6:

#### Passed by Object, Pointer, and Reference

- // passed by object void f(int a) { ...} int main() { int b; ...; f(b); }
- // passed by object void h(A a) { ...} int main() { A aa; ...; f(aa); }
- // passed by pointer
  void g(int \*p) { ... }
  int main() { int \*q = ...; f(q); }
- // passed by reference void k(A& a) { ...} int main() { A aa; ...; k(aa); }

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### Passed by Object, Pointer, and Reference

[Rule of thumb] Making an '=' (i.e. copy) from the passed argument in the caller, to the parameter of the called function.

```
void f1(int a)
{ a = 20; }
void f2(int& a)
{ a = 30; }
void f3(int* p)
{ *p = 40; }
void f4(int* p)
{ p = new int(50); }
void f5(int* & p)
{ p = new int(60); }
```

```
main()
{
    int a = 10;
    int* p = &a;
    int a1,a2,a3,a4,a5;
    f1(a); a1 = a;
    f2(a); a2 = a;
    f3(p); a3 = *p;
    f4(p); a4 = *p;
    f5(p); a5 = *p;
}
```

What are the values of a1, a2, a3, a4, and a5 at the end?

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

10

a2 = 30; a3 = 40; a4 = 40; a5 = 60;

a1 = 10;

# Summary #1: Passed by pointer or passed by reference

 If you have some data to share among functions, and you don't want to copy (by '=') them during function calling, you can use "passed by pointers"

```
class A {
   int _i; char _c; int *_p; ...
};
void f(A *a) { ... }
...
int main() {
   A *a = ...;
   f(a);
}
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

# Summary #1: Passed by pointer or passed by reference

2. However, if originally the data is not a pointer type, "passed by pointers" is kind of awkward. You should use "passed by references"

```
class A {
    int _i; char _c; int *_p; ...
};
void f(A *a) { ... }
void g(A& a) { ... }
...
int main() {
    A a = ...; // an object, not a pointer
    f(&a); // Awkward!! C style \(\omega\)
    g(a); // Better!!
}
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

12

#### Summary #1:

#### Passed by pointer or passed by reference

3. But, sometimes we just want to share the / data to another function, but don't want it to modify the data.

```
int main() {
    A a = ...;
    g(a);
}

void g(A& a) { ... }
// "a" may get modified by g()

→ Using "const" to constrain!!
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### Part II: More on "Variables"

- "const" keyword
- Array vs. pointers
- Pointer arithmetic
- Memory sizes of variables
- ◆ Return value of a function
- ◆ Compilation issues
- ◆ Compiler preprocessors

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

14

#### **Key Concept #1: Const**

- Const is an adjective
  - When a variable is declared "const", it means it is "READ-ONLY" in that scope.
    - → Cannot be modified
- Const must be initialized
  - const int a = 10; // OK
  - const int b; // NOT OK const variables must be initialized!!
  - int i; // Not initialized...
    const int j = i; // Is this OK?
    const int& k = i; // Is this OK?
    f(j); // f(int m) { ... }; Is this OK?
    i = 10; // will j, k be changed? Is this OK?
- "const int" and "int const" are the same
- ◆ "const int \*" and "int \* const" are different !!

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### What? const \*& #\$&@%#q

- ♦ Rule of thumb
  - Read from right to left
- 1. f(int\* p)
  - Pointer to an int (integer pointer)
- 2. f(int\*& p)
  - Reference to an integer pointer
- 3. f(int\*const p)
  - Constant pointer to an integer
- 4. f(const int\* p) = f(int const \* p)
  - Pointer to a constant integer
- 5. f(const int\*& p)
  - Reference to a pointer of a constant int
- 6. f(const int\*const&p)
  - Reference to a constant pointer address, which points to a constant integer

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

17

classes could use const method operator () to serve as functors, as long as it don't modify its own data fields.

Passed in a reference to a constant object 'c'

→ 'c' cannot be modified in the function

const A& B::blah (const C& c) const {...}

Return a reference to a constant object

→ The returned object can then only call constant methods

This is a constant method, meaning this object is treated as a constant during this function

→ None of its data members can be modified

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

18

only classes could have constant methods.

#### **Key concept #2: The Impact of const**

Supposed "\_data" is a data member of class MyClass
void MyClass::f() const
{
 \_data->g();

- Because this object is treated as a constant, its data field "\_data" is also treated as a constant in this function
  - → "g()" must be a constant method too!!
- Compiler will signal out an error if g() is NOT a const method
- [Coding tip] If we really want a member function to be a readonly one (e.g. getXX()), putting a "const" can help ensure it

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

19

#### Const vs. non-const??

 Passing a non-const argument to a const parameter in a function

```
void f(const A& i) { ... }
void g(const A j) { ... }
int main() {
   A a; ...
   f(a); // a reference of "a" is treated const in f()
   g(a); // a copy of "a" is treated const in g()
}
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### Const vs. non-const??

 Passing a const argument to a non-const parameter in a function

```
void f(A& i) { ... }
void g(A j) { ... }
int main() {
  const A a(...);
  f(a); // Error → No backdoor for const
  g(a); // a copy of "a" is treated non-const in g()
}
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

21

#### Const vs. non-const??

Non-const object calling a const method

```
T a;
```

- a.constMethod(); // OK
- "a" will be treated as a const object within "constMethod()"
- Const object calling non-const method const T a;
  - a.nonConstMethod(); // not OK
  - A const object cannot call a non-const method
    - → compilation error

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### Casting "const" to "non-const"

const T a;
a.nonConstMethod(); // not OK
Trying...

- 1. T(a).nonConstMethod();
  - Static cast; OK, but may not be safe (why?)
  - Who is calling nonConstMethod()? explicitly calling copy constructor, so it's the newly build instance of the class calling nonConstMethod(), so
- 2. const cast<T>(a).nonConstMethod(); compile okay.
  - Compilation error!!
  - "const\_cast" can only be used for pointer,
     reference or a pointer-to-data-member type
- const\_cast<T \*>(&a)->nonConstMethod();
  - OK, but kind of awkward

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

23

#### const\_cast<T>() for pointer-to-const object

```
const T* p;
p->nonConstMethod(); // not OK
```

→ const\_cast<T\*>(p)->nonConstMethod();
A const object can now call non-const method

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### const class object (revisited)

◆ Remember:

const A& B::blah (const C& c) const {...}

- When an object of class B calls this member function, this object will become a "const class object".
- That is, the B's data members will be treated as const (i.e. can't be modified) in this function.
- Also, "this" cannot call non-const functions in "blah()", nor can the data members call non-const functions.

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

26

#### **Key Concept #3:**

#### "mutable" --- a back door for const method

- However, sometimes we MUST modify the data member in a const method
  - void MyClass::f() const
    {
     \_flags |= 0x1; // setting a bit of the \_flags
    }
  - In such case, declare "\_flag" with "mutable"
     keyword
     often used in graph traversals, such that it could be modified even in const methods.

mutable unsigned flag;

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### **Key Concept #4: Array vs. Pointer**

- An array variable represents a "const pointer"
  - int a[10]; treating "a" as an "int \* const"
     a = anotherArr; // Error; can't reassign "a"
  - int \*p = new int[10];
     p = anotherPointer; // Compile OK, but memory leak!
     p = new int(20); // also compile OK, but memory leak!
- An array variable (the const pointer) must be initialized
  - Recall: "const" variable must be initialized
  - Key: the size of the array must be known in declaration
  - int a[10]; // OK, as the memory address is assigned.
     int a[10] = { 0 }; // Initialize array variable and its content int a[]; // NOT OK; array size unknown int a[] = { 1, 2, 3 }; // OK array size determined by RHS

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

20

#### Const pointer vs. pointer to a const

```
int a = 10;
const int c = 10;
a = c; // OK
c = a; // NOT OK; even though 10 = 10
int a[10] = { 0 };
int b[10];
int *c;
const int *d; // This is OK!
int *const e; // Error: uninitialized
b = a; // Error
c = a; d = a; // OK
e = a; // Error
void f(const int* i) { ... }
int main() {
   int * const a = new int(10);
   f(a); // Any problem? it's okay...
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

## More about int [] and int\*

```
int a[10] = { 0 }; // type of a: "int *const"
int *p = new int[10];
*a = 10;
*p = 20; // OK
*(a + 1) = 20;
*(a++) = 30; // Compile error; explained later
a = p; // Compile error; non-const to const
p = a; // OK, but memory leak...
*(p++) = 40; // OK, but what about "delete [] p''?
int *q = a;
q[2] = 20;
*(q+3) = 30;
*(q++) = 40;
             // OK
delete a; // compile error/warning; runtime crash...
delete []p; // compile OK, but runtime crash (p = a)
delete []q; // compile OK, but may get fishy result
What about:
int a = 10; int *p = &a; ... delete p;
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

30

### **Key Concept #5: Pointer Arithmetic**

- '+' / '-' operator on a pointer variable points to the memory location of the next / previous element (as in an array)
  - int \*p = new int(10); int \*q = p + 1; // memory addr += sizeof(int)
  - A \*r = new A;
     r -= 2; // memory addr -= sizeof(A) \* 2
- ◆ For an array variable "arr", "arr + i" points to the memory location of arr[i]
  - int arr[10];\*(arr + 2) = 5; // equivalent to "arr[2] = 5"

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### (Recapped) Key Concept #6: Memory Sizes

- ◆ Basic "memory size" unit → Byte (B)
  - 1 Byte = 8 bit
- ◆ 1 memory address → 1 Byte
  - Like same sized apartments
- Remember: the variable type determines the size of its memory
  - char, bool: 1 Byte(addr += 1)
  - short, unsigned short: 2 Bytes(addr += 2)
  - int, unsigned, float: 4 Bytes (addr += 4)
  - double: 8 Bytes (addr += 8)
  - long long: 8 Bytes(addr += 8)

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

32

#### **Key Concept #7: Size of a Pointer**

- Remember:
  - A pointer variable stores a memory address
  - What is the memory size of a memory address?
- The memory size of a memory address depends on the machine architecture
  - 32-bit machine: 4 Bytes
  - 64-bit machine: 8 Bytes
- ◆ Remember: 1 memory address → 1 Byte
  - → The memory content of the pointer variables
  - : For 32-bit machine, the last 2 bits are 0's : For 64-bit machine, the last 3 bits are 0's

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### **Key Concept #8: Memory Alignment**

♦ What are the addresses of these variables? int \*p = new int(10); // let addr(p) = 0x7fffe84ff0e0 char c = 'a'; int i = 20; int \*pp = new int(30); char cc = 'b'; int \*ppp = pp; int ii = 40; char ccc = 'c'; char cccc = 'd'; int iii = 30;

→ Given a variable of predefined type with memory size S (Bytes), its address must be aligned to a multiple of S

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

34

## **Key Concept #9: Return value of a function**

- ◆ Every function has a return type. At the end of the function execution, it must return a value or a variable of the return type.
  - "void f()" means no return value is needed
- 1. Return by object

```
MyClass f(...) {
    MyClass a;...; return a; }
MyClass b = f(...); okay
MyClass& c = f(...); error
// What's the diff? Is it OK?
// The referenced object must have a
// valid memory addr outside f()
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### Return by Object, Pointer, and Reference

```
2. Return by pointer
     MyClass* f(...) { MyClass* p;...; return p; }
      MyClass* q = f(...);
// Should we "delete q" later?
3. Return by reference (reference to whom?)
      MyClass& f(...; return r; }
      // r cannot be local (why?)
      MyClass& s = f(...); // <-----|
      [NOTE] Should NOT return the reference of a
      local variable
int& f() { int a; ...; return a; }
need to check it's valid;
      compilation warning
                                   often used with "return (*this)" such that
      MyClass& MyClass::f(...)
{...; return (*this); }
                                   we could easily concatenate operator and
                                   functions
      MyClass s;
      MyClass& t = s.f(...); // <-----|
      MyClass v = s.f(...); // What's the diff?
```

Prof. Chung-Yang (Ric) Huang

37

38

### When is "return by reference" useful?

Data Structure and Programming

Data Structure and Programming

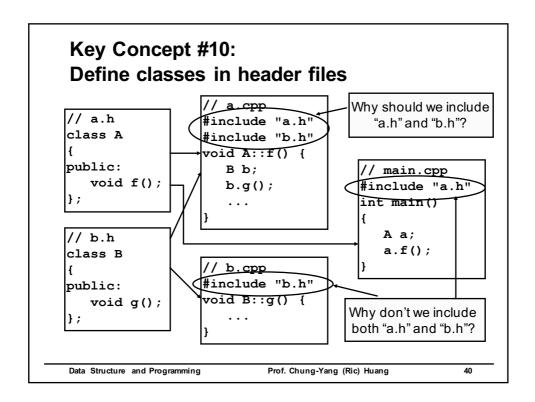

Prof. Chung-Yang (Ric) Huang

### Remember in a software project...

- ◆ Your program may have many classes...
- ◆ You should create multiple files for different class definitions ---
  - .h (header) files
    - → class declaration/definition, function prototype
  - .cpp (source) files
    - → class and function implementation
  - Makefiles
    - → scripts to build the project

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

### Key Concept #11: "#include"

- ◆ A compiler preprocessor
  - Process before compilation
  - Perform copy-and-paste
- ♦ This is NOT OK

```
• // no #include "b.h"
  class A {
        B _b;
};
```

- ♦ This is OK
  - // no #include "b.h"
    class B; // forward declaration
    class A {
     B \*\_b;
    };
- → The rule of thumb is "need to know the size of the class"!!

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

41

#### Key Concept #12: #include " " or <> ?

- ◆ Standard C/C++ header files
  - Stored in a compiler-specified directory
     e.g. /usr/local/include/c++/8.2.0/
- #include <> will search it in the standard header files
- #include "" will search it in the current directory ('.'), or the directories specified by "-I" in g++ command line.

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

## **Key Concept #13: Undefined or Redefined Issues**

- ◆ Undefined errors for variable/class/type/function
  - The following will cause errors in compiling a source file --int i = j; // If j is not declared before this point
    A a; // If class A is not defined before this point
    A \*a; // If class A is not declared before this point
    goo(); // If no function prototype for goo() before this point
  - The following is OK when compiling each source file, but will cause error during linking if goo() is NOT defined in any other source file --

```
int goo(); // forward declaration
...
int b = goo();
```

- Redefined errors
  - Variable/class/function is defined in multiple places
  - May be due to multiple inclusions of a header file

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

43

#### Declare, Define, Instantiate, Initialize, Use

- 1. Declare a class identifier / function prototype
  - class MyClass;
  - void goo(int, char);
- 2. Define a class / function / member function
  - class MyClass { ... };
  - void goo() { ... }
  - void MyClass::goo2() { ... }
- 3. Instantiation (= Declaration + definition) (variable / object)
  - int a;
  - MyClass b;
- 4. Initialization (during instantiation) (variable / object)
  - int a = 10;
  - MyClass b(10);
  - . Used (variable / object / function)
    - a = ...; or ... = a;
    - goo();
    - b.goo2();

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

### Key Concept #14: "extern" in C++

- Remember, static variables and functions can only be seen in the file scope → cannot be seen in other file
- What if we want to access (global) variables or functions across other .cpp files?

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

45

#### **Using External Variables and Functions**

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

### **Key Concept #15: Forward Declaration**

#### [Bottom line]

Sometimes we just want to include part of the header file, or refer to some declarations

- → We don't want to include the whole header file
- → To reduce:
  - 1. Executable file size
  - 2. Compilation time due to dependency

```
e.g.

// MyClass.h

class HisClass; // forward declaration

class HerClass; // forward declaration

class MyClass
{

    HisClass* _hisData; // OK
    HerClass _herData; // NOT OK; why?
};
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

47

#### **Key Concept #16: Namespace**

```
◆ e.g.
    namespace MyNameSpace {
        int a;
        void f();
        class MyClass;
    } // Note: no ';'
        namespace MyNS = MyNameSpace; // alias
        Must declare in global scope
        int main()
        {
            namespace XYZ { ... } // Error!!
        }
}
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### **Using namespace**

```
1. void g() {
      MyNameSpace::a = 10;
    } // "::" is the scope operator
2. using MyNameSpace::a;
    void g() {
      a = 10;
    }
3. using namespace MyNameSpace;
    void g() {
      a = 10;
      f();
    }
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

49

### More about namespace declaration

or outside (e.g. f()) "namespace {...}.

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### Summary #2: Declare, Define, & Use

- If something is declared, but not defined or used, that is fine. (Compilation warning)
- ◆ If something is used before it is defined or declared → compile (undefined) error.
- ◆ If something is defined in other file, you can use it only if you forward declare it in this file. BUT you cannot define it again in this file → compile (redefined) error.
  - Variable → "extern"
  - Function → prototype, with or without "extern"
- ◆ If something is declared, but not defined, in this file, you can use it and the compilation is OK. BUT if it is not defined in any other file → linking (undefined) error.

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

51

#### Key Concept #17: #define

- #define is another compiler preprocessor
  - All the compiler preprocessors start with "#"
- "#define" performs pre-compilation inline string substitution
- "#define" has multiple uses in C++
  - 1. Define an identifier (e.g. #define NDEBUG)
  - Define a constant (e.g. #define SIZE 1024), or substitute a string
  - 3. Define a function (Macro)

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### "#define" for an Identifier

 To avoid repeated definition of a header file in multiple C/C++ inclusions

```
#ifndef MY_HEADER_H
#define MY_HEADER_H
// header file body...
// ...
#endif
```

2. Conditional compilation

#ifndef NDEBUG
// Some code you want to compile by default
// (i.e. debug mode)
// For optimized mode,
// define "NDEBUG" in Makefile.
#endif

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

54

#### "#define" for a Constant or a String

- #define <identifier> [tokenString]
  - e.g.

```
#define SIZE 1024
#define CS_DEFAULT true
#define HOME_DIR "/home/ric"
(why not /home/ric?)
```

- Advantage of using "#define"
  - Correct once, fix all
- ♦ What's the difference from "const int xxx", etc?
  - Remember: "#define" performs pre-compilation inline string substitution
  - "const int xxx" is a global variable
    - → Fixed memory space
    - → Better for debugging!!

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### "#define" for a MACRO function

- #define <identifier>(<argList>) [tokenString]
  - e.g. #define MAX(a, b) ((a > b)? a: b) // Why not "((a > b)? a: b)"?
  - e.g. // Syntax error below!! Why?? #define MAX(int a, int b) ((a > b)? a: b)
- Disadvantage
  - "#define" MACRO function is difficult to debug!!
    - → Cannot step in the definition (Why??)
  - Use inline function (i.e. inline int max(int a, int b)) instead

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

56

#### Part III: More on "Classes"

- Class, struct, union, enum
- ◆ Bit-slicing
- Class wrapper
- "static" keyword

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### Key Concept #1: "struct" in C++

- [Note] "struct" is a C construct used for "record type" data
  - Very similar to "class" in C++, but in C, there is no private/public, nor member function, etc.
- However, "struct" in C++ inherits all the features of the "class" construct
  - Can have private/public, member functions, and can be used with polymorphism
  - The only difference is: the default access privilege for "struct" is public

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

58

#### Key Concept #2: "union" in C++

- At any given time, contains only one of its data members
  - To avoid useless memory occupation
  - i.e. data members are mutual exclusive
    - Use "union" to save memory
  - size = max(size of its data members)
- ◆ A limited form of "class" type
  - Can have private/public/protected, data members, member functions
    - default = public
  - Can NOT have inheritance or static data member

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

## Example of "union"

```
union U
{
  private:
    int _a;
    char _b;
  public:
    U() { _a = 0; }
    int getA() const
        { return _a; }
    void setA(int i)
        { _a = i; }
    char getB() const
        { return _b; }
    void setB(char c)
        { _b = c; }
};
```

♦ What is the output???

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

60

#### **Anonymous union**

- Union can be declared anonymously
  - i.e. Omit the type specifier

```
main()
{
    union {
        int _a;
        char _b;
    };
    int i = _a;
    char j = _b;
}
```

- → used as non-union variables
- → What if it is NOT anonymous?

```
class A {
   union # {
      int _a;
      double _b;
   };
   #__t:
   void f() {
      if (_t_a>
      10)...
   };
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

## Key Concept #3: Another ways to save memory: memory alignment and bit slicing

- Note: in 64-bit machine, data are 8-byte aligned What are "sizeof(A)" below ?
  - class A { char \_a; };
  - class A { int \_i; bool \_j; int\* \_k; }
  - class A { int i; bool j; int\* k; char l; }
- Recommendation
  - Pack the data in groups of "sizeof(void\*)", or ---
  - Use bit-slicing to save memory

```
class A {
   int _id: 30;
   int _gender: 1;
   int _isMember: 1;
   void f() { if (_isMember) _id += ...; }
};
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

62

#### How about bit-slicing for pointers?

- ◆ No, size of pointers is fixed. You cannot bit slice them.
- One "tricky" way to save memory is to use the fact that pointer addresses are multiple of 8's (for 64-bit machines)

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### A Closer Look at the Previous Example

- Important concepts:
  - No extra memory usage when wrapping a pointer variable with a class
  - However, you gain the advantages in using constructor/destructor, operator overloading, etc, which are not applicable for pointer type variables.
    - → BddNode a, b, c;...; c = a & b;
  - The LSBs can be used as flags or stored other information.

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

65

## Summary #2: "class", "struct", & "union"

- In C++, data members are encapsulated by the keywords "private" and "protected"
  - Make the interface between objects clean
    - Reduce direct data access
  - Using member functions: correct once, fix all
- Struct and class are basically the same, except for their default access privilege
- Union: no inheritance nor static data member

class struct union

Default access private public public

Enum: user-defined type for named constants

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### **Key Concept #4: Enum**

 A user-defined type consisting of a set of named constants called enumerators

- By default, first enumerator's value = 0
- ◆ Each successive enumerator is one larger than the value of the previous one, unless explicitly specified (using "=") with a value

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

67

### Scope of "enum"

 Enumerators are only valid within the scope it is defined

```
    e.g.
    class T {
        enum COLOR { RED, BLUE };
    };
    PED/PLUE is only seen within
```

- → RED/BLUE is only seen within T
- To access enumerator outside of the class, use explicit class name qualification
  - e.g. void f() { int i = T::RED; }
  - → But in this case, the enum must be defined as <u>public</u>

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### Common usage of "enum"

- 1. Used in function return type
  - Color getSignal() { ... }
- 2. Used as "status" and controlled by "switch-case"

```
ProcState f() { ...; return ...; }
...
ProcState state = f();
switch (state) {
   case IDLE : ...; break;
   case ACTIVE: ...; break;
} // What's the advantage??
```

Used as "bit-wise" mask

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

69

#### **Bitwise Masks**

```
◆ To manipulate multiple control "flags" in a single integer
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

## Key Concept #5: "#define" vs. "enum"

- 1. #define RED 0
  #define BLUE 1
  #define GREEN 5
- What's the difference in terms of debugging?
  - Using "#define" → Can only display "values"
  - Using "enum" → Can display "names"

Recommendation: using "enum"

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

71

#### Recall: Size of a Class

 The size of a class (object) is equivalent to the summation of the sizes of its data members

→ sizeof(A) = sizeof(B) + sizeof(C\*);

 Wrapping some variables with a class definition DOES NOT introduce any memory overhead!!

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### **Key Concept #6: Class Wrapper**

- To create a "record" type with a cleaner interface
  - e.g. When passing too many parameters to a function, creating a class to wrap them up.
  - → Making sure data integrity (checked in constructor)
  - → Creating member functions to enact assumptions, constraints, etc.

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

73

### **Key Concept #6: Class Wrapper**

- 2. To manage the memory allocation/deletion of pointer variables
  - Recap: pointer data member will not be explicitly constructed in class constructor
  - Memory allocation/deletion problems for pointer variables
    - There may be many pointer variables pointing to the same piece of heap memory
    - The memory should NOT be freed until the "last" pointer variable become useless (HOW DO WE KNOW!!?)
    - What about the pointer (re-)assignment?
  - Recap: The memory of an object variable is allocated when entering the scope, and released when getting out.
  - Recap: The heap memory must be explicitly allocated and deleted.

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### **Object-Wrapped Pointer Variables**

If your program contains pointer-pointed memory that is highly shared among different variables

- ◆Keep the reference count
- ◆Pointer → internal class (e.g. class NodeInt)
  Object → user interface (e.g. class Node)

```
class NodeInt {
                       // a private class
   friend class Node;
                                  Data _data
   Data
              data;
                                  size_t _refCnt
             left;
   Node
   Node
              right;
   size t
              refCnt;
                                   node
};
                              _data
                          Data
                                           Data
                                               data
class Node {
                          size_t
                              _refCnt
                                           size t
                                                _refCnt
   NodeInt * node;
};
                          node
                                           node
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

75

#### **Object-Wrapped Pointer Variables**

```
Node::Node(...) {
    ...
    if (!_node) _node = newNode(...);
    _node->increaseRefCnt();
}
Node::~Node() { resetNode(); }
Node::resetNode() {
    if (_node) {
        _node->decreaseRefCnt();
        if (_node->getRefCnt() == 0) delete _node;
    }
}
Node& Node::operator = (const Node& n) {
    resetNode();
    _node = n._node;
    _node->increaseRefCnt();
}
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### **Key Concept #6: Class Wrapper**

 To keep track of certain data/flag changes and handle complicated exiting/exception conditions

```
void f() {
    x1.doSomething();
    if (...) x2.doSomething();
    else { x1.undo(); return; }
    ...
    x2.undo(); x1.undo();
}

>Very easy to miss some actions...
void f() {
    XKeeper xkeeper; // keep a list in xkeeper
    xkeeper.doSomething(x1);
    if (...) xkeeper.doSomething(x2);
    else return;
} // ~XKeeper() will be called
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

77

#### Key Concept #7: "static" in C++

- As the word "static" suggests, "static xxx" should be allocated, initialized and stay unchanged throughout the program
  - → Resides in the "fixed" memory

#### However.

- ◆ The keyword "static" is kind of overloaded in C++
- 1. Static variable in a file
- 2. Static variable in a function
- 3. Static function
- 4. Static data member of a class
- 5. Static member function of a class

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

### So, what does "static" mean anyway?

- \*static" here, refers to "memory allocation" (storage class)
  - The memory of "static xxx" is allocated before the program starts (i.e. in fixed memory), and stays unchanged throughout the program

#### [cf] "auto" storage class

 Memory allocated is controlled by the execution process (e.g. local variables in the stack memory)

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

79

## **Key Concept #8:** Visibility of "static" variable and function

- 1. Static variable in a file
  - It is a file-scope global variable
  - Can be seen throughout this file (only)
  - Variable (storage) remained valid in the entire execution
- 2. Static variable in a function
  - It is a local variable (in terms of scope)
  - Can be seen only in this function
  - Variable (storage) remained valid in the entire execution
- 3. Static function
  - Can only be seen in this file
- Static variables and functions can only be seen in the defined scope
  - Cannot be seen by other files
  - No effect by using "extern"

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

#### [Note] Storage class vs. visible scope

- Remember, "static" refers to static "memory allocation" (storage class)
  - We're NOT talking about the "scope" of a variable
- The scope of a variable is determined by where and how it is declared
  - File scope (global variable)
  - Block scope (local variable)
- → However, the "static" keyword does constrains the maximum visible scope of a variable or function to be the file it is defined

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

81

## Key Concept #9:

#### "static" Data Member in a Class

- Only one copy of this data member is maintained for all objects of this class
  - All the objects of this class see the same copy of the data member (in fixed memory)
  - (Common usage) Used as a counter

```
class T
{
    static int _count;
public:
    T() { _count++; }
    ~T() { _count--; }
};

int T::_count=0;
// Static data member must be initialized in some
// cpp file => NOT by constructor!!! (why?)
```

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

## Key Concept #10: "static" Member Function in a Class

- ◆ Useful when you want to access the "static" data member but do not have a class object
  - Calling static member function without an object
    - e.g. T::setGlobalRef();
  - No implicit "this" argument (no corresponding object)
  - Can only see and use "static" data members, enum, or nested types in this class
    - Cannot access other non-static data members
- ◆ Usage

```
T::staticFunction(); // OK
object.staticFunction(); // OK
T::staticFunction() { ... staticMember... } // OK
T::staticFunction() { ... this... } // Not OK
```

- T::staticFunction() { ... nonStaticMember... } // Not OK
- T::nonstaticFunction() { ... staticMember...} // OK

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

83

#### Example of using "static" in a class

```
class T
{
   static unsigned _globalRef;
   unsigned _ref;

public:
   T() : _ref(0) {}
   bool isGlobalRef() { return (_ref == _GlobalRef); }
   void setToGlobalRef() { _ref = _global Ref; }
   static void setGlobalRef() { _globalRef++; }
}
```

 Use this method to replace "setMark()" functions in graph traversal problems (How??)

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang

## Key Concept #11: static\_cast<T>(a)... Cast away static?? ⊗

Data Structure and Programming

Prof. Chung-Yang (Ric) Huang
